

Vigyázok Rád

The house that speaks up when something is wrong

One big button on the wall, one app on the phone, and a house whose rooms alert each other. Not a platform for everyone — a tool that can be fitted to every life differently.

What works today

MEASURED, WITH TWO CONSOLES, SEPTEMBER 2026

- **Segítség app** (Android, beta): one press → a message with your location to your helpers; 999/101/111 one tap away.
- **Wall console**: a big HELP button, “I’m fine”, a light switch — set up with a QR code in two minutes.
- **The house alerts**: “HELP – Sickroom” on every console in the house, with an “On my way!” button — 10 seconds, two rooms, one button.
- **Nothing disturbs at night**: the screen dims, the first touch only wakes it; when an alert comes, the wall lights up.
- **Your data stays in the house**: local network, its own web page on every console, complete without any cloud.

Who it is for

- the grandmother looking for her glasses on her forehead — **one** button she finds blind
- the convalescent, the patient confined to four walls — messages, medicines, “I’m fine” to the family
- the wheelchair user working from home — the lamp from the bed, the neighbour at one press
- the child who locked the bathroom door — one button that says where it came from

What is coming

PLAN — THE ORDER IS SET BY WHAT OUR TESTERS NEED

- **Sound and notifications on the phone**: the house’s alert also rings in the app — the console is silent, the phone is not.
- **The neighbour in the help chain**: whoever can be there in 30 seconds hears it before family 200 km away.
- **A smart medication dispenser** — not a reminder: it *confirms* that the dose left its compartment. In full on the second page.
- **Messages** inside the house and to the family — preset buttons and free text.
- **Smart switches, bulbs, leak and smoke sensors** on the house network — from the console and the app.
- **Wearable beacon** (watch): falls, “I’m stuck”, a call from the wrist.
- **Server: an automatic dispatch centre** — devices join it *by themselves*. The alert does not stop at the front door: it goes down the help chain in order, and if nobody answers it moves on. Plus health monitoring, escalation, history, many houses on one screen.
- **What we undertake — and what we do not**: *we build* the system and hand it over working. The 24-hour watch, the dispatch service itself, has to be run by someone who specialises in that. We make the tool, not the service.
- **Three languages**: Hungarian, German, English — on the console, in the app, on the web.

Two rooms, one button: the Sickroom alerts, the Office answers — “On my way!”

The home screen: I’m fine · Light · HELP — with the room’s name

What we do not compromise on

- What saves one life is noise to another — so everything is configurable, nothing is mandatory.
- The system detects and tells — it does not act in your place.
- Affordable, off-the-shelf hardware — the money goes into setup and care, not into the box.
- What we call “working” here, we measured. What we call “plan” is a plan.

About the medication dispenser

in design — its electronics are being built now

The dangerous case is not someone forgetting to take their medication. It is someone remembering that they took it.

- The reminder is the **easy part** — every phone can do that. What matters is what happens **after** the reminder, and that is where most products stop too early.
- The memory is there; it is simply **wrong** — and a reminder cannot help with that, because in their mind there is nothing left to be reminded about.
- So this device **does not ask, and does not trust the answer**. It confirms on two **independent levels** that the dose actually left its compartment. Until that confirmation exists, it does not let the matter drop.
- If the signal is ignored for long enough while the capsules are still in the compartment, a **notification** goes to a family member or carer — through the Segítség app or the console. Someone who can pick up the phone and ask.
- The people who need this most are often the ones who see the least. So: **large type, real contrast, tactile buttons** — and colour is never the only signal.

One principle, twice

THESE TWO DEVICES ARE NOT TWO SEPARATE IDEAS

- **For the medication dispenser:** a reminder is not enough — it needs a **confirmation**.
- **For the console:** an alarm is not enough — it needs an **answer**.

Both come out in the same place: a signal on its own is only a hope. It becomes help when **something comes back** — a confirmation that it happened, or an “I am coming!” that someone has set off. Most devices stop at the signal. Closing the loop is the harder half — and the point of the whole thing.

Where to see more

- **vigyazokrad.hu** — the same text in all three languages, with photographs and a **108-second film** of the two consoles (no sound; everything the film shows is also written out).
- On the page the **text size is adjustable**, the **screen reader switches language** with the page, and colour is never the only signal anywhere.
- This brochure can be **downloaded** there, in all three languages.
